WUL + MoMo › Me

STRATEGIC PARTNERSHIP PROPOSAL · CONFIDENTIAL

WUL + MoMo›Me × Sorted Wallet

WUL + MoMo›Me is one company: a settlement gateway that turns any Sorted balance into money on a Cameroonian Mobile Money number — through one signed API, with the rails, routing and reconciliation handled. Sorted joins as a business-settlement client.

Every Number. Every Network. One Payment Layer.

28 October 2026

THE STRATEGIC OPPORTUNITY

A wallet balance is only as useful as the places it can land.

Sorted holds value for its users. In Cameroon, the place that value has to reach is a Mobile Money number — MTN or Orange — because that is what rent, school fees and a market trader accept. The distance between those two facts is the opportunity.

What Sorted owns

The customer, the balance, the product experience, and the trust that comes with being the app someone already uses.

What the last mile costs

Operator onboarding, prefunded float per carrier, payout and collection adapters, FX, reconciliation, compliance, and an on-call rota for when a vendor fails. Each one is a quarter of work before a single payment lands.

What a gateway changes

Sorted integrates once. The rails, routing, retries, settlement and reconciliation sit behind a signed API and a webhook contract that does not change when a rail does.

THE CONNECTIVITY CHALLENGE

The hard part is not the payment. It is everything that happens when one fails.

Mobile Money does not reverse. A payout that leaves is gone, and a payout that silently does not leave is worse — because the balance has already been debited somewhere. Most integration effort goes here, not into the happy path.

Four questions every integration has to answer

- **Did it actually land?** A provider callback is a hint, not proof.
- **Is the rail down, or is our balance zero?** Opposite responses; identical symptom.
- **Is this the right person?** A mistyped digit is a stranger with your money.
- **Can we prove it, a month later?** Reconciliation is what a regulator asks for.

Why it compounds

- Each operator and aggregator answers differently, and changes without notice.
- Float is prefunded **per carrier** — an MTN balance tells you nothing about Orange.
- Quotes expire; a rate held too long is a loss, held too briefly is a failed payment.
- A vendor can disappear, and the integration above it must not move when one does.

MEET WUL + MOMO›ME

A payment orchestration layer, in production, with the receipts in source.

Every figure on this slide is counted from the platform or read from the live service on 28 October 2026.

17

public /v1 endpoints — intent, routes, execute, status, webhooks, reconciliation

3

independent rail registries: crypto inbound, Mobile Money payout, Mobile Money collection

116

automated suites in the release gate — every deploy passes all of them

4

pay-in methods: Lightning, on-chain BTC, USDT, USDC

What it does today

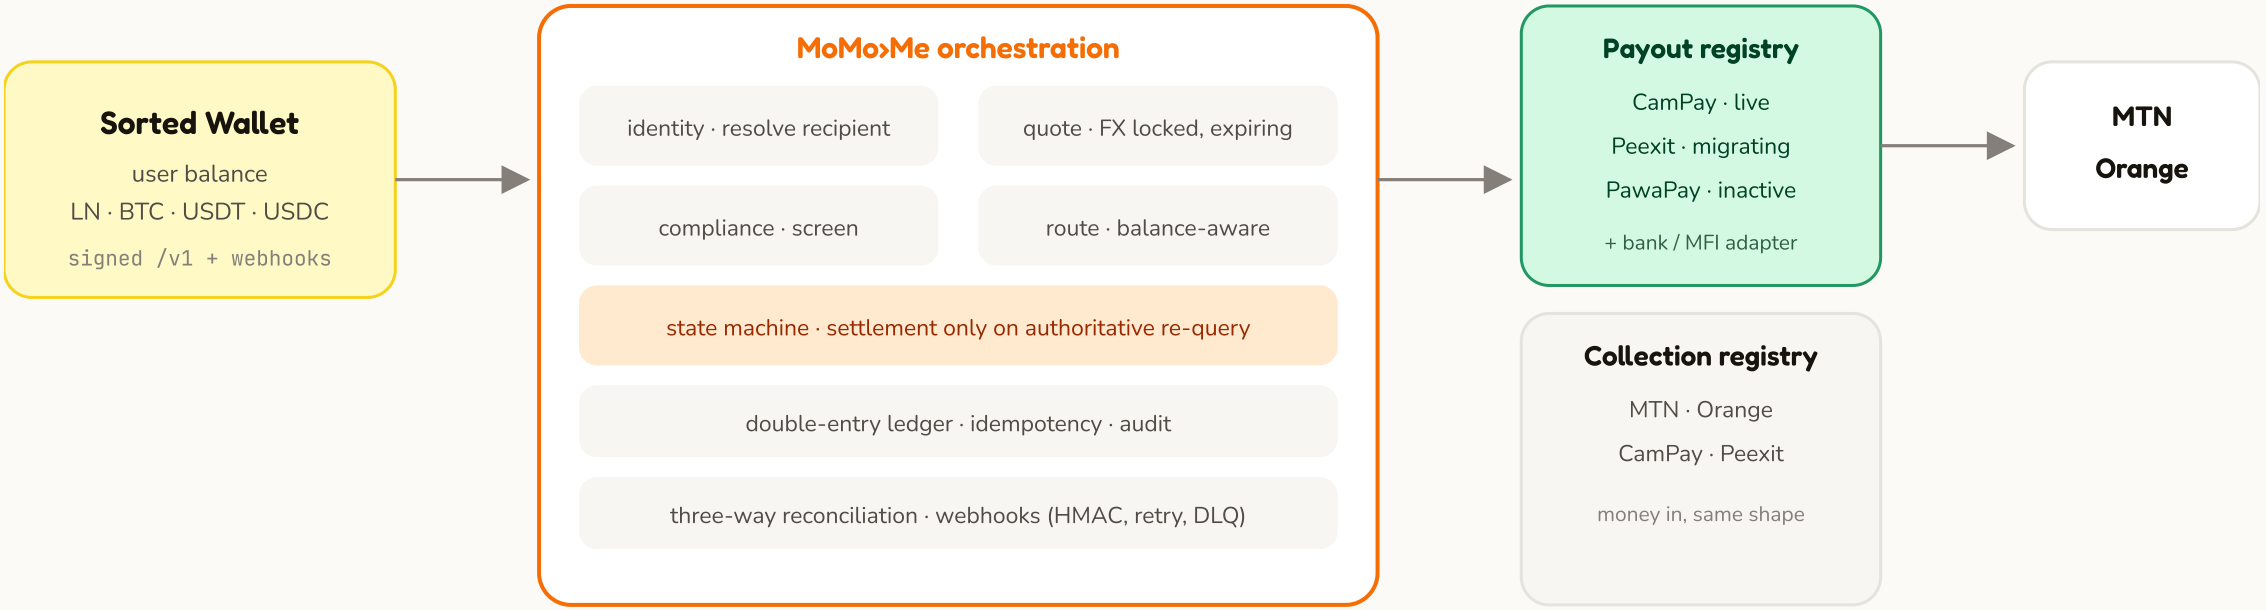

Takes a crypto or stablecoin payment in, locks an FX rate for a bounded window, routes to a funded Mobile Money rail, settles to an MTN or Orange number, and reconciles all three legs continuously.

How a rail is added

Implement an adapter interface and append it to a registry array. Routing, health tracking, failover, idempotency and reconciliation are inherited, not rewritten. A bank or MFI with a request/response API is the same shape.

THE TECHNOLOGY

One intent, three registries, one ledger — and a boundary Sorted never has to look past.

Source: `routes/v1.ts`, `adapters/payouts.ts`, `adapters/collect.ts`, `adapters/index.ts`, `core/stateMachine.ts`. Rail status as at 28 Oct 2026 — see slide 14.

WHY OUR STRATEGIES ALIGN

Sorted owns the customer. We own the last mile. Neither is cheap to rebuild.

DIMENSION	SORTED BRINGS	WUL + MOMO›ME BRINGS	JOINT OPPORTUNITY
Distribution	An installed wallet base and the user relationship	Settlement into MTN and Orange through one signed API	Cash-out becomes a feature of Sorted, not a separate app
Infrastructure	Custody, balances, user authentication	Rail registries, routing, idempotency, reconciliation	Neither side builds the other's half
Technology	Wallet UX and transaction initiation	A stable partner vocabulary that survives rail changes	Sorted's integration does not move when a vendor does
Customer experience	Trust already earned in-app	Recipient name verification before a payment is confirmed	Fewer payments to the wrong number — the error that cannot be undone
Revenue	Volume and pricing power with its users	Per-transaction economics with a negotiated partner rate	A margin split both sides can model before launch
Regional expansion	Ambition beyond one market	A market-by-market adapter pattern, Cameroon first	Francophone corridors on a shared integration

WHY MOMO›ME IS THE RIGHT STRATEGIC FIT

Four properties that are difficult to retrofit, and are already load-bearing here.

Unknown is never treated as zero

A balance we cannot read returns `null`, never `0`. The router refuses rather than guesses, and the operator is told which of the two it was. Most integrations collapse these, and send people hunting an empty wallet when the real fault was a dead host.

Settlement follows proof, not notification

A provider callback is a hint that prompts an authoritative re-query. Only that re-query can complete a payment. A forged or replayed callback cannot release money.

A superseded attempt cannot settle

When a payout fails over to a second rail, a late verdict from the first is ignored. Without this, a refund can be issued against money another rail is still carrying — a real defect, found and fixed with a regression test that fails against the old code.

The recipient is checked before the money moves

Recipient verification returns the operator-registered name behind a number, through whichever provider can answer — independent of which rail will settle the payment.

Each property is covered by automated tests in the release gate. Sources are listed in the evidence register accompanying this deck.

WHAT WE CAN BUILD TOGETHER

Three levels, each one standing on its own.

Level 1 — Immediate

Cash-out from Sorted to Mobile Money.

Sorted calls the existing `/v1` surface; we settle to MTN or Orange and report every state change by signed webhook. Nothing new has to be built on either side to begin a pilot.

Level 2 — Medium term

Cash-in, and per-partner economics.

The collection registry gives Sorted top-ups from the same numbers. Per-partner margin reporting, partner-specific pricing, and a reconciliation report Sorted's finance team can close a month against.

Level 3 — Strategic

More corridors, more destinations.

The same adapter shape reaches banks and MFIs, and additional Francophone markets. Sorted participates in a connectivity layer rather than commissioning a one-off integration.

Levels 2 and 3 are **proposed**. Level 1 uses capabilities that exist today.

THE PARTNERSHIP ARCHITECTURE

One boundary, drawn so that our problems never become Sorted's problems.

Sorted's responsibility

- Custody of user balances and the in-app experience
- Initiating a payment intent with a destination and amount
- Receiving and acting on webhook state changes
- First-line user support, using the reference we return

WUL + MoMo›Me's responsibility

- Recipient resolution, quoting and FX rate lock
- Rail selection, retries and failover across payout rails
- Settlement to the Mobile Money number, and its proof
- Reconciliation, compliance screening and the audit record

The contract at the boundary

A signed `/v1` API with per-organisation credentials and scopes; idempotency keys on every money-moving call; HMAC-signed webhooks with retries and a dead-letter queue; and a stable status vocabulary that does not change when a rail is added, replaced or fails. **When a vendor of ours disappears, Sorted's integration does not change.** That is the whole point of the boundary.

PARTNERSHIP USE CASES

Four, ordered by how soon they could carry real volume.

USE CASE	WHAT THE USER DOES	WHAT IT NEEDS	READINESS
Cash-out to Mobile Money	Sends part of a Sorted balance to any MTN or Orange number in Cameroon	Existing `/v1` surface; funded payout float	AVAILABLE NOW
Verified recipient send	Sees the registered name behind the number before confirming	Identity chain — live and returning names	AVAILABLE NOW
Cash-in / top-up	Funds a Sorted balance from a Mobile Money number	Collection registry; partner-facing flow	EXTEND
Merchant disbursement	Sorted pays many recipients at once — payroll, incentives, refunds	Batch semantics over existing intents	BUILD

"Available now" means the capability is implemented and exercised by automated tests.

COMMERCIAL OPPORTUNITY

A fee Sorted can see through, and a margin Sorted keeps.

THE MODEL — BUSINESS PARTNER TIER

$1,500 per month per partner organisation, plus **0.5%** on every transfer, on every rail. Sorted enters on this tier, as a business-settlement client.

Rail and network cost is **passed through at cost**, on its own line — never folded into our rate. On this corridor it runs about **1.0%**. Where a leg carries exchange exposure, the spread is quoted separately and at cost: **150 bps** on Lightning and stablecoins, **280 bps** on-chain, covering the window the rate is locked for.

Minimum transfer **500 XAF**. Quotes hold for **10 minutes** (Lightning, USDT) and **15 minutes** on-chain. Above an agreed monthly volume the 0.5% steps down on a schedule fixed before launch — Sorted's margin widens as the corridor grows.

Constants read from `shared/domain.ts` and `core/platform/billing.ts`, not assumed.

ILLUSTRATIVE ONLY — NOT A FORECAST

ON A TRANSFER OF 25 000 XAF	VALUE
Sorted's price to its user — **Sorted sets this**	625 XAF
Rail and network cost, passed through	250 XAF
WUL + MoMo›Me fee, 0.5%	125 XAF
Sorted keeps, per transfer	250 XAF · 40%
All-in cost to Sorted	1.5%

These are inputs, not results. No transaction volume, revenue or customer figure is claimed anywhere in this deck, and no existing wallet integration is — Sorted would be our first wallet partner. Volume and end-user pricing are Sorted's to supply; we will model jointly against them.

GO TO MARKET

Sorted's channel, our rails — launched into one corridor before any other.

Who we start with

A bounded cohort of Sorted users in Cameroon, cash-out only, with per-transaction and daily caps set jointly. Small enough to watch every payment; large enough to prove the economics.

How it reaches users

Inside Sorted, as a destination in a flow the user already understands. No new app, no new credential, no redirect. We are infrastructure and should be invisible.

What we provide

A sandbox with deterministic scenario numbers, an API reference, a partner hub for the integrating team, and a named operational contact for the pilot window.

What success at this stage looks like

Not volume. A pilot succeeds if every payment reaches a terminal state we can explain, every failure has a reason the user could act on, and the month reconciles to the last franc across all three legs.

IMPLEMENTATION ROADMAP

Five phases. Indicative timings, not commitments.

PHASE	DELIVERABLE	OWNER	INDICATIVE	GATE TO PASS
1 · Alignment	Confirm use case, corridor, caps, success metrics; compliance and regulatory posture agreed	Both	2–3 weeks	Signed scope
2 · Integration	Credentials and scopes, sandbox end-to-end, webhook delivery, idempotency conventions	Sorted + MoMo›Me	3–4 weeks	Green sandbox run
3 · Controlled pilot	Live cohort under caps; daily reconciliation; incident drill against a rail failure	Both	4–6 weeks	Clean month-end
4 · Commercial launch	Caps raised, rate fixed, support path published, operational reporting in place	Both	Following quarter	Agreed unit economics
5 · Expansion	Cash-in, further corridors, bank and MFI destinations	Both	Beyond	Reviewed jointly

Phase 3 deliberately includes a rehearsed rail failure. We would rather show Sorted how the system behaves under one than describe it.

RISK, TRUST AND GOVERNANCE

What happened this month, and what it tells you about the system.

A partner deck that omits this would be discovered in diligence. We would rather present it, because the behaviour under failure is the strongest thing we have to show.

The failure

On 24 October a payout vendor withdrew its API hostnames from DNS without notice. A second rail was unfunded. For four days MoMo›Me could not settle a Mobile Money payout at all. Recipient verification, which used the same vendor, went dark with it.

What held

No payment was lost, stranded or misdirected. The flow refused every method before taking money, told the sender nothing had been charged, and disabled the confirm button. Unknown was never read as zero; no payout was released without an authoritative re-query.

What it exposed — and what changed

The defects were in how the failure was **described**, not in how money was handled. The sender was told "no funded payout rail" when the truth was that no rail could be reached; the console reported an unreachable rail as operational. Both were fixed and deployed on 28 October, each with a regression test that fails against the previous behaviour. The vendor has since issued a new gateway and is being reconnected.

Current status, 28 Oct 2026: one payout rail live and authenticating, float unfunded; one rail migrating; one inactive. Recipient verification restored and returning names.

MEASURING SUCCESS

Measures both sides can read from the same data.

MEASURE	DEFINITION	WHY IT MATTERS	OWNER
Settlement rate	Payments reaching a terminal success state, over all initiated	The only number a user feels	MoMo›Me
Time to terminal state	Median and 95th percentile from intent to settled or refunded	Pending is the state that generates support load	MoMo›Me
Explained failure rate	Failures carrying a reason the user could act on	An unexplained failure is two support contacts	Both
Reconciliation variance	Unmatched value at month end across all three legs	Target is zero; anything else is a finding	Both
Verified-recipient share	Payments confirmed against a returned operator name	Directly reduces irreversible misdirected payments	Both
Contribution per transfer	Fee less rail and network cost	Decides whether the corridor scales	Both

Baselines are set together during Phase 1 and measured from the pilot's first live payment.

STRATEGIC EXPANSION

Cameroon is a corridor, not the thesis.

More destinations

A bank or MFI with a request/response API is the same adapter shape as an aggregator. Routing, reconciliation and failover are inherited. The constraint is licensing posture, not protocol.

More corridors

Francophone markets share operators, currency behaviour and regulatory contours. Each is an adapter plus a compliance review, not a rebuild.

More origins

The pay-in side is its own registry. New assets and networks attach without touching the settlement path Sorted integrates against.

What we are explicit about

Connecting to a national switch requires licensed participation, held either by us or by a sponsoring institution. We hold no such posture today, and this deck claims none. It is a decision to take together, with eyes open, not a capability to assume. The posture we *do* hold is on the next slide.

COMPLIANCE AND REGULATORY POSTURE

Who is accountable, what is monitored, and what we are applying for.

The previous slide says what we do not hold. This one says what we do.

Settlement through licensed partners

Every Mobile Money leg is executed by a payment institution licensed in the market it settles in — CamPay today, with Peexit and PawaPay as alternates. We orchestrate, route and reconcile; we do not hold user funds on the payout leg.

Named accountability

A compliance officer and a deputy are appointed, with standing responsibility for AML/CFT decisions, sanctions and PEP outcomes, and for filing suspicious-transaction reports to ANIF.

Continuous monitoring — Sumsub

Identity verification, sanctions and PEP screening and ongoing transaction monitoring run through Sumsub. Screening is a gate inside the payment flow, not a periodic batch: a payment that cannot be screened does not settle.

Licence pathway — COSUMAF

A COSUMAF licence application is the route we are taking to hold posture in our own name rather than borrowing a sponsor's. Until it is granted, every regulated act sits with a licensed partner.

The audit record

Every screening result, compliance decision and filing is written to a hash-chained, tamper-evident log, aligned to CEMAC Règlement 02/24 — a month can be reconstructed in order and shown to a regulator, with any alteration detectable.

THE PARTNERSHIP PROPOSAL

What we are asking Sorted to consider.

We propose

- A **technology and settlement partnership**, not a software licence
- Scope one: **cash-out from Sorted to MTN and Orange in Cameroon**
- A **bounded pilot** under jointly agreed caps
- The **business partner tier** — $1,500 per month plus 0.5% per transfer, with rail cost passed through at cost and a volume step-down fixed before launch
- Joint monthly review against the measures on slide 15

We are asking Sorted for

- A named technical and a named commercial counterpart
- Expected volume, average transfer size and Sorted's own end-user price, so both margins can be modelled honestly
- Agreement on the pilot cohort and its caps
- Confirmation of Sorted's compliance requirements for a settlement partner
- A decision on Phase 1 — scope, not commitment

What we commit to before any live payment

A funded payout float with per-carrier balances visible to both parties; a rehearsed failover drill; and written confirmation of rail status on the day of launch. We will not ask Sorted to send a user's money through a rail we cannot currently reach.

WUL + MoMo › Me

Sorted holds the balance. We make it land.

A wallet is judged by whether money arrives. That is the part we have built, tested, and proven under failure.

Every Number. Every Network. One Payment Layer.
